RL workshop March 2021 System Identification: An Overview

Build mathematical models from observed input and output signals

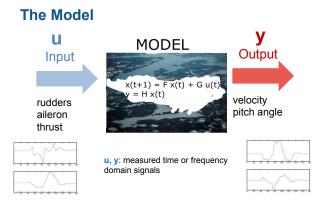

Lennart Ljung

An Introductory Example: System

The System

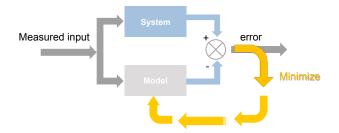

An Introductory Example 2: Model

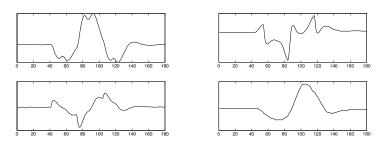

An Introductory Example 3: Model Fitting

The System and the Model

Data from the Gripen Aircraft

Output: Pitch Inputs: Canard, Elevator, Leading Edge Flap

▶ How do the control surface angles affect the pitch rate?

Using All Inputs

 u_1 canard angle; u_2 Elevator angle; u_3 Leading edge flap;

$$y(t) = -a_1 y(t - T) - a_2 y(t - 2T) - a_3 y(t - 3T) - a_4 y(t - 4T)$$

$$+ b_1^1 u_1(t - T) + \dots + b_1^4 u_1(t - 4T)$$

$$+ b_2^1 u_2(t - T) + \dots + b_1^3 u_3(t - T) + \dots + b_4^3 u_3(t - 4T)$$

Estimate 16 parameter using half of the data record – Simulate the model using all inputs.

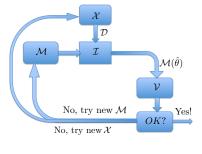

Dashed line: Actual Pitch rate. Solid line: 10 step ahead predicted pitch rate, based on the fourth order model from all inputs.

First half estimation data - second half validation data.

System Identification: Issues

- ► Select a class of candidate models
- ▶ Select a member in this class using the observed data
- ► Evaluate the quality of the obtained model
- Design the experiment so that the model will be "good".

The System Identification Flow

 \mathcal{X} : The Experiment

 \mathcal{D} : The Measured Data

M: The Model Set

I: The Identification Method

 \mathcal{V} : The Validation Procedure

Models: General Aspects for Dynamical Systems

- A model is a mathematical expression that describes the connections between measured inputs and outputs, and possibly related noise sequences.
- ► They can come in many different forms
- ightharpoonup The models are labeled with a parameter vector θ
- ▶ A common framework is to describe the model as a predictor of the next output, based on observations of past input-output data.

```
Observed input–output (u, y) data up to time t: Z^t
Model described by predictor: \mathcal{M}(\theta): \hat{y}(t|\theta) = g(t, \theta, Z^{t-1}).
```

Estimation

If a model, $\hat{y}(t|\theta)$, essentially is a predictor of the next output, is is natural to evaluate its quality by assessing how well it predicts: Form the *Prediction error* and measure its size:

$$\varepsilon(t,\theta) = y(t) - \hat{y}(t|\theta), \quad \ell(\varepsilon(t,\theta)) = \varepsilon^{2}(t,\theta)$$

How has it performed historically?

$$V_N(\theta) = \sum_{t=1}^N \ell(\varepsilon(t,\theta))$$

Which model in the structure performed best?

$$\hat{\theta}_N = \arg\min_{\theta \in D_M} V_N(\theta)$$

Often coincides with the Maximum Likelihood Estimate.

Linear Regressions

The linear regression:

$$y(t) = \varphi^{T}(t)\theta + e(t)$$

y(t) and $\varphi(t)$ known/measured at time t. Find a good value of θ ! This covers many useful systems and signals models:

- AR: $\varphi^T(t) = [-y(t-1)...-y(t-n)]$
- ► ARX:

$$\varphi^{T}(t) = [-y(t-1)...-y(t-n), u(t-1)...u(t-m)]$$

"Semi-physical", non-linear models:

$$y(t) = a_1 y^3(t-1) + a_2 y(t-1)u_1(t-1) + a_3 \log u_2(t-2)$$

The (Recursive) Least Squares Estimate

$$\hat{\theta}(t) = \arg\min \sum_{j=1}^{t} (y(j) - \varphi^{T}(j)\theta)^{2} = \left[\sum_{j=1}^{t} \varphi(j)\varphi^{T}(j)\right]^{-1} \sum_{j=1}^{t} y(j)\varphi(j)$$
$$= R^{-1}(t)f(t)$$

... can be exactly rewritten

$$\hat{\theta}(t) = \hat{\theta}(t-1) + R^{-1}(t)\varphi(t)\varepsilon(t)$$

$$\varepsilon(t) = y(t) - \varphi^{T}(t)\hat{\theta}(t-1)$$

$$R(t) = R(t-1) + \varphi(t)\varphi^{T}(t)$$

Check Algebra!

$$\hat{\theta}(t) = R^{-1}(t)f(t) = R^{-1}(t)(f(t-1) + \varphi(t)y(t))
= R^{-1}(t)(R(t-1)\hat{\theta}(t-1) + \varphi(t)y(t))
= R^{-1}(t)[(R(t) - \varphi(t)\varphi^{T}(t))\hat{\theta}(t-1) + \varphi(t)y(t)]
= \hat{\theta}(t-1) + R^{-1}(t)\varphi(t)[y(t) - \varphi^{T}(t)\hat{\theta}(t-1)])$$

Note that

$$P(t) = R^{-1}(t) = [R(t-1) + \varphi(t)\varphi^{T}(t)]^{-1}$$

$$P(t) = P(t-1) + \frac{P(t-1)\varphi(t)\varphi^{T}(t)P(t-1)}{1 + \varphi^{T}(t)P(t-1)\varphi(t)}$$

So ...

Recursive Least Squares

$$\hat{\theta}(t) = \hat{\theta}(t-1) + P(t)\varphi(t)\varepsilon(t)$$

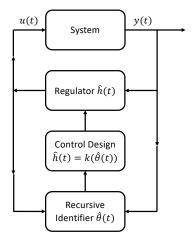

$$\varepsilon(t) = y(t) - \varphi^{T}(t)\hat{\theta}(t-1)$$

$$P(t) = P(t-1) + \frac{P(t-1)\varphi(t)\varphi^{T}(t)P(t-1)}{1 + \varphi^{T}(t)P(t-1)\varphi(t)}$$

Note that the updating is driven by $\varphi(t)\varepsilon(t)=-\frac{d}{d\theta}[\varepsilon^2(t)]$ (the reward for a good model! Compare with Gradient Policy RL!

Adaptive Control

Use a recursive estimator to build a system model at all times. Compute a controller k based on the current model!

Example (used in RL) Measure all states

$$x(t+1) = Ax(t) + Bu(t) + w(t)$$
$$y(t) = x(t) + e(t)$$

Example:

$$A = \begin{bmatrix} 1.01 & 0.01 & 0 \\ 0.01 & 1.01 & 0.01 \\ 0 & 0.01 & 1.01 \end{bmatrix} \qquad B = I$$

Identification code: [Matlab System identification Toolbox]

```
ms = idss(rand(3,3),rand(3,3),eye(3,3),zeros(3,1))
ms.Structure.C.Free = zeros(3,3) [ % C fixed to identity]
m = ssest(data,ms,ssestOptions,'DisturbanceModel', 'est');
A = m.A, B = m.B;
```

Identification Result

Note that system is unstable; it must be run under stabilizing feedback!

Test: 100 observations, Additive observation noise with variance 1 in each channel:

$$\hat{A} = \begin{bmatrix} 1.0016 & 0.0065 & 0.0076 \\ 0.0267 & 1.0192 & 0.0101 \\ 0.0370 & 0.0419 & 0.9672 \end{bmatrix} \quad A = \begin{bmatrix} 1.01 & 0.01 & 0 \\ 0.01 & 1.01 & 0.01 \\ 0 & 0.01 & 1.01 \end{bmatrix}$$

$$\hat{B} = \begin{bmatrix} 1.0101 & 0.0140 & -0.0094 \\ 0.0058 & 0.9899 & -0.0120 \\ 0.0121 & 0.0194 & 0.9607 \end{bmatrix} \quad B = I$$

Summary

- ➤ Traditional Control approach to RL: Build a model and use that for control design. ("Model Building RL").
- System identification is a general and versitile tool to build models from data.
- Discuss next time (April 6) Pro's and con's of this traditional approach compared to the new techniques.
